Radical Subtraction

What Happens When All Input Stops

Most historical accounts of religious mysticism focus on theological disputes, ecclesiastical politics, or emotional devotionalism. These treatments treat monastic asceticism as a curious psychological aberration—a medieval obsession with physical self-punishment or an escape from societal trauma.

When examined through the lenses of modern cognitive neuroscience and information theory, however, the writings of the major Christian contemplatives reveal an entirely different mechanism. These individuals were not self-destructive neurotics; they were empirical investigators of human consciousness executing a precise, reproducible protocol of signal-to-noise optimization.

The human brain is a prediction machine chronically saturated by high-amplitude noise: sensory inputs, social standing anxieties, narrative memory loops, and biological comfort-seeking. This ceaseless internal monologue is maintained by the Default Mode Network (DMN), centered in the posterior cingulate cortex and medial prefrontal cortex. Under ordinary conditions, the high amplitude of this autobiographical noise floor drowns out subtle, low-amplitude neural dynamics.

By systematically applying radical sensory and social subtraction—fasting, physical enclosure, prolonged darkness, rhythmic breath synchronization, and apophatic cognitive silencing—the contemplatives drove the denominator of Shannon's channel capacity equation down toward zero. What they reported on the other side of that sensory silence was not cognitive disintegration or delirium, but an extraordinary, unshakeable state of unified awareness.

CHAPTER 1

The Cell on the Tagus

John of the Cross and the Doctrine of the Dark Night (Toledo, 1577–1578)

Shortly after midnight on December 2, 1577, armed Carmelite friars arrested thirty-five-year-old Juan de Yepes y Álvarez in Ávila. They blindfolded him, tied him to a mule, and marched him eighty miles across the freezing Castilian plateau to Toledo. When he refused to abandon Teresa of Ávila's reform of primitive barefoot poverty and silent prayer, the prior locked him inside a ten-by-six-foot converted closet adjacent to the monastery privy. He had no change of clothes, no heating in winter, and no light except for a three-inch slit high in the stone wall that caught reflected midday sun for roughly twenty minutes. The rest was absolute darkness and the stench of waste.

In human neurobiology, the ongoing narrative of personal identity is maintained by the Default Mode Network (DMN). The DMN consumes roughly 20 percent of the brain's total metabolic energy while an individual is at rest, continuously rehearsing past autobiographical regrets and projecting future social scenarios. When external sensory input is cut off by sensory deprivation and caloric starvation, the metabolic anchor of this network dissolves. In modern neuroimaging studies of deep sensory deprivation, the metabolic activity of the posterior cingulate cortex drops sharply, causing the

boundaries between the subjective ego and the external environment to dissolve.

Every Friday evening, the friars led John to the refectory. He knelt on the cold stone while the community chanted the *Miserere* and struck his bare back with knotted leather whips until his shoulders were raw and bleeding. Returned to his cell without medical attention, his tunic rotted against his wounds. He lived on stale bread and sardine scraps, contracting dysentery and scurvy. Yet in that dark room, without paper, ink, or a candle, he composed thirty stanzas of the *Cántico Espiritual*—widely regarded as some of the most luminous love poetry in the Spanish language—revising and memorizing every rhyme in the pitch black.

In Claude Shannon's mathematical theory of communication, channel capacity is determined by the signal-to-noise ratio:

$$C = B \log_2 \left(1 + \frac{S}{N}\right)$$

Human consciousness functions as an information channel saturated by high-amplitude noise: physical comfort-seeking, language, social rivalries, and fear. If subtle cognitive invariants are low-amplitude, they are drowned out by the noise floor (N). Most spiritual systems attempt to reach awareness by amplifying the signal (S) through sensory grandeur, cathedral architecture, music, and ritual, frequently driving the sensory channel into overload. John's

doctrine of *nada* (nothingness) operated exclusively on the denominator. By systematically driving noise down toward zero ($N \to 0$), subtle invariants that are completely imperceptible in normal life became unmistakable.

By August 1578, knowing his physical body was failing from dysentery and fever, John decided to leave. Using a small copper clasp loosened from his prayer book, he patiently loosened the screws around the hinges of his wooden cell door during his twenty minutes of daily light. On the night of August 14, he pushed the door until the screws gave way, climbed to an outer balcony overlooking the sheer gorge of the Tagus River, tied strips of his bed blanket together, and dropped twelve feet into an adjacent convent garden. He walked into the dawn carrying thirty stanzas of poetry wrapped in a rag under his arm.

CHAPTER 2

The Anchorhold of Norwich

Julian of Norwich and the Confinement of the Hazelnuts (1373–1416)

Attached to the south wall of St. Julian's Church in Norwich stood a stone chamber measuring roughly twelve feet square, with its exterior door mortared shut. It had three small openings: a squint cut through the interior stone wall so the occupant could see the church altar, a shuttered service hatch opening into a servant's room for food and waste, and a small barred window hung with a black curtain facing the public street. Inside lived a woman whose legal name has not survived—known only as Julian, after the church to whose wall she was sealed.

In May 1373, at age thirty, she had lain in bed dying of an acute febrile illness while a parish priest held a copper crucifix before her failing eyes. Over forty-eight hours of hypoxia and fever, she experienced sixteen vivid perceptual sequences before making an unexpected recovery. Shortly afterward, she petitioned the Bishop of Norwich for permanent enclosure as an anchorite. During the ceremony, the bishop chanted the Office of the Dead, sprinkled grave dust over her head, led her into the cell, and ordered masons to brick up the doorway. Under medieval canon law, she was legally dead to the world, forbidden to step outside the twelve-foot room until her burial beneath its floor more than forty years later.

This physical confinement acted as a forty-year perceptual reduction experiment. In sensory neuroscience, when an observer's external spatial environment is held completely invariant over decades, cortical processing shifts away from dorsal-stream spatial navigation toward deep episodic synthesis and conceptual integration. Inside the cell, while the Black Death and subsequent plague waves killed half the population of Norwich outside her window, Julian spent twenty years analyzing the sixteen visions of 1373. She produced two successive manuscripts—the *Short Text* and the *Long Text* of *Revelations of Divine Love*—the earliest surviving works in the English language written by a woman.

Her central perceptual observation examined the fragile boundary of finite existence:

"He showed me a little thing, the quantity of a hazelnut, lying in the palm of my hand, and it was as round as any ball. I looked upon it with the eye of my understanding, and thought, 'What may this be?' And the answer came: 'It is all that is made.' I marveled how it could last, for methought it might suddenly have fallen to naught for littleness. And I was answered in my understanding: 'It lasteth, and ever shall, for God loveth it.'"

In Julian's observation, physical scale carries no ontological privilege. The entire macroscopic cosmos—stars, kingdoms, and centuries—is compressed into the visual angle of a hazelnut resting on human skin: finite, contingent, and perpetually on the verge of vanishing into nothingness, yet held stable by a single underlying invariant. When pilgrims,

plague survivors, and fellow mystic Margery Kempe came to the black-curtained street window in 1413 to ask how to survive a collapsing world, Julian answered from behind the cloth with the sentence that closed her thirty-year manuscript: “All shall be well, and all shall be well, and all manner of thing shall be well.”

CHAPTER 3

The Interior Castle

Teresa of Ávila and the Neurodynamics of the Seventh Mansion (1577, Toledo)

For the last twenty years of her life, Teresa of Ávila worked through chronic neuro-inflammatory seizures, partial paralysis, severe tinnitus, and violent cardiac palpitations. Once, during a four-day coma in her twenties, she had been pronounced dead, her grave dug in the convent yard, and hot wax dripped onto her eyelids before she suddenly woke. Yet between 1562 and 1582, bouncing across the rutted mule tracks of Castile and Andalusia in covered wooden carts, she personally founded seventeen reformed Discalced Carmelite convents against fierce opposition from the Spanish Inquisition and papal nuncios.

In the summer of 1577, confined by church authorities to the convent of San José in Toledo at age sixty-two, her confessor Jerónimo Gracián ordered her to write an instruction manual mapping the stages of silent prayer for her nuns. Working at a pine table over eight weeks of Castilian summer heat, writing rapidly without going back to revise, she produced *Las Moradas del Castillo Interior* (*The Interior Castle*). Where earlier medieval writers relied on vague allegorical poetry, Teresa dissected internal cognitive states with the empirical precision of a clinical neurologist.

Teresa modeled human consciousness as a spherical crystal fortress containing seven nested concentric rings of rooms—"mansions"—surrounding a quiet central chamber. Modern autonomic neuroscience recognizes her progression across these seven rooms as a systematic modulation of the nervous system from sympathetic fight-or-flight arousal to stabilized parasympathetic vagal dominance:

1. **The First to Third Mansions (Active Discursive Effort)**: The mind remains bound to external sensory chatter, social anxiety, and deliberate verbal reasoning. Cortical executive networks expend continuous metabolic effort trying to force attention still.
2. **The Fourth Mansion (The Prayer of Quiet)**: The physiological inflection point. Teresa contrasts two methods of filling a stone water basin: hauling water through long aqueducts by muscle power versus water rising silently from an underground spring directly beneath the basin. In autonomic physiology, this marks the engagement of the ventral vagal brake—respiration slows, heart rate variability (HRV) increases, and the frontoparietal control network releases its grip.
3. **The Fifth and Sixth Mansions (Suspension and Somatic Rapture)**: Characterized by transient autonomic instability: sudden peripheral vasoconstriction (cooling of the hands and feet), muscular catalepsy, and sensory gating where external sounds and pinpricks register only faintly.

4. **The Seventh Mansion (Stabilized Integration)**: All dramatic somatic raptures, trances, and visual hallucinations disappear completely. The practitioner inhabits a quiet, continuous baseline of unshakeable equanimity while simultaneously handling complex external logistics, lawsuits, and convent construction.

In Stephen Porges's polyvagal framework, the mammalian myelinated vagus nerve originating in the nucleus ambiguus acts as an active pacemaker brake that calms metabolic threat responses without inducing dorsal-vagal fainting or dissociation. Teresa explicitly warned her prioresses never to mistake visions, trances, or emotional ecstasies for spiritual maturity. She classified many ecstatic visions as physical infirmities—"weakness of the head" exacerbated by fasting and sleep loss, which modern neurology identifies as temporal-lobe discharges or migraine auras. When a nun claimed to have reached union with God in prayer, Teresa ignored the visionary report and checked the kitchen ledger: as she wrote in her final chapter, "Martha and Mary must work together."

CHAPTER 4

The Desert Pillar

Simeon Stylites and the Physics of Vertical Isolation (423–459 AD, Syria)

In the spring of 423 AD, a thirty-three-year-old shepherd turned monk named Simeon walked into the limestone hills of Telanissos (modern Qal'at Sim'an, Syria), forty miles east of Antioch. Expelled from a Syrian monastery for extreme fasting that alarmed his abbot, Simeon had spent three years inside a dry mountain cistern and three years chained to a hillside boulder. As word spread across the Roman East, thousands of pilgrims, sick travelers, and Bedouin nomads crowded around his rock from dawn to dusk, pressing forward to tear threads from his sheepskin tunic. Seeking a way to remain in public view without being crushed by horizontal human contact, Simeon engineered a vertical solution.

He had local quarrymen cut a limestone column six cubits (roughly ten feet) tall, topped by a narrow stone platform six feet square enclosed by a wooden balustrade. He climbed up, pulled the ladder away, and stayed. As the crowds at the base grew louder, Simeon had masons replace the column in three successive stages—rising to twelve cubits, twenty-two cubits, and finally forty cubits (sixty feet) above the Syrian plain. Exposed to freezing winter gales and summer sun, he stood atop that thirty-six-square-foot platform for thirty-seven years until his death in 459 AD.

In his fifth-century chronicle *Historia Religiosa*, Bishop Theodoret of Cyrrhus—who visited the pillar in person—recorded the physical mechanics of Simeon's routine. Simeon never lay down; he stood upright or bowed repeatedly from the waist, touching his forehead to his toes. Theodoret noted that a companion counted 1,244 consecutive bows before losing track. Once a week, local boys hoisted a bucket of water and soaked lentils up the shaft on a rope pulley. Chronic venous stasis from decades of continuous standing caused severe crural ulcers across his lower legs; in later hagiographies, chroniclers embellished these wounds with stories of Simeon replacing fallen maggots onto the sores.

Stripped of hagiographic legend, Simeon's sixty-foot column operated on the psychophysics of sensory adaptation governed by the Weber-Fechner Law:

$$\frac{\Delta I}{I} = k$$

where the just-noticeable difference in a sensory stimulus (ΔI) is proportional to the background baseline intensity (I). In a ground-level town, the nervous system is continuously reset by shifting close-range stimuli: faces within arm's reach, whispered conversations, cooking smoke, and physical jostling. By lifting himself sixty feet into empty air, Simeon reduced background social and tactile noise (I) near zero. His visual and auditory horizon locked onto slow plan-

etary constants: solar elevation, wind across limestone, and star tracks.

Paradoxically, those sixty feet of vertical distance turned an illiterate Syrian shepherd into the highest court of appeal in the Eastern Roman Empire. Because Simeon owned no land, accepted no coin, and could not be reached by guards or assassins without climbing sixty feet in front of thousands of witnesses, his neutrality was absolute. From the balustrade, he shouted down arbitration rulings on water rights, ordered interest rates capped at six percent (half the Roman legal maximum), dictated diplomatic letters to Emperor Theodosius II, and settled tribal blood feuds for caravan leaders gathered at the base of the stone shaft. When he died standing against the railing on September 2, 459 AD, the commander of the Eastern Roman army marched six hundred soldiers from Antioch to escort his body before desert tribes could carry it away.

CHAPTER 5

The Apophatic Cloud

The Anonymous English Contemplative and the Erasure of Memory (c. 1375)

Somewhere in the East Midlands of England around 1375, an anonymous country priest drafted a seventy-five-chapter vernacular manual for a twenty-four-year-old student and opened it with a strict prohibition: the book must never be read by clever talkers, curious scholars, or anyone unwilling to sit still in mental darkness. The author left no name, monastery, or Latin title on the parchment, calling it simply *The Cloud of Unknowing*.

For the preceding two centuries, European university theology had been dominated by the kataphatic (affirmative) architecture of high scholasticism. Following Thomas Aquinas, scholars at Paris and Oxford built vast logical systems—the *Summae*—by stacking positive propositions: defining the divine through chains of Aristotelian causes, attributes, and analogies.

The anonymous English author rejected the entire affirmative apparatus. Human language and conceptual imagination, he argued, evolved to handle physical objects in three-dimensional space—food, tools, threats, and social status. When the human intellect tries to grasp unconditioned reality using mental pictures or philosophical definitions, it

manufactures a cognitive counterfeit. Accumulating more theological concepts does not bring the mind closer to reality; it merely thickens the static.

To clear the channel, the manual prescribes a two-layer attentional filter:

- **The Cloud of Forgetting**: The practitioner must push every autobiographical memory, every sensory image, every philosophical argument, and even devout meditations on the saints down beneath a dense "cloud of forgetting." If a clever thought or virtuous memory surfaces, the practitioner must tread it down immediately before it spawns a narrative chain.
- **The Cloud of Unknowing**: Above the practitioner sits a dark, featureless void where the analytical intellect cannot operate. Rather than trying to think through this darkness, the practitioner holds bare, non-verbal attention steady against it—anchoring the mind with a single one-syllable word (such as *God* or *Love*) used not as a topic for reflection, but as a rhythmic shield to block discursive thought from restarting.

In computational neuroscience, this protocol targets the loop between the hippocampus (which continuously replays episodic memories) and the language centers of the left inferior frontal gyrus (Broca's area), which maintain the internal verbal monologue. When a subject suppresses inner multi-word syntax and refuses to elaborate incoming memory associations, predictive coding loops in the default mode network starve for token transitions.

The author was fiercely skeptical of visionary highs and bodily sensations, warning his student in blunt Midland prose:

"Beware that you do not take this work physically. For when I speak of darkness, I do not mean an absence of physical light such as when a candle is put out. And when I speak of a cloud, I do not mean a cloud made of moisture in the air. Those who strain their physical imagination to stare into an artificial interior blackness only inflame their brains and breed fantastical delusions."

When the manuscripts circulated quietly among Carthusian Charterhouses in the fifteenth century, monks copied the text anonymously, preserving a purely operational guide to shutting down the brain's narrative generator.

CHAPTER 6

The Dialectic of the Nothing

Meister Eckhart and the Breakthrough of the Ground (1314–1326, Cologne)

To call God a “being,” Johannes Eckhart argued from his Dominican pulpit in Cologne, was a logical error—because any individual being is finite, bounded, and defined by contrast with what it is not. In the winter of 1326, at age sixty-six, Eckhart—former Master of Sacred Theology at the University of Paris and vicar-general of Dominican convents across Bohemia and Saxony—was summoned before an inquisitorial tribunal convened by Heinrich von Virneburg, the Archbishop of Cologne. It was the first time in medieval history that a Dominican inquisitor-general had been put on trial for heresy.

Presented with forty-nine suspect propositions pulled from his vernacular German sermons, Eckhart refused to recant. Speaking at the Dominican church in Cologne on February 13, 1327, he read a public Latin declaration stating that his accusers had mistaken formal metaphysical distinctions for heresy because they could not think past subject-object grammar.

In Paris, Eckhart had occupied the academic chair once held by Thomas Aquinas, mastering Latin scholastic disputation. Yet when he was sent to Strasbourg and Cologne to preach

to Beguine laywomen, weavers, and Dominican nuns, he dropped Latin terminology and forged a new philosophical vocabulary in Middle High German. He attacked the transactional economy of late medieval religion—treating prayer as a merchant's contract where fasting, alms, and relics were traded to an external deity in exchange for favors: "Some people want to see God with their eyes as they see a cow, and to love him as they love their cow—for the milk and the cheese and their own profit."

At the center of Eckhart's cognitive model was the distinction between Gott (God as a personal, relational object conceived by human thought) and Gott*heit* (the Godhead, or *Grund*—the unconditioned, featureless ground prior to all distinction). So long as an observer stands on one side of a mental boundary looking at "God" as an object on the other side, the observer remains trapped inside dualistic representation. That is why Eckhart shocked his Cologne congregation with the paradox: "Therefore I pray to God that he may make me free of 'God.'"

In formal logic and cybernetics, this is the boundary problem of self-reference: a representational model inside a system cannot contain the unconditioned ground that generates both the observer and the model. To move past the representation requires what Eckhart termed the *Durchbruch* (the breakthrough) via *Abgeschiedenheit* (detachment) and *Gelassenheit* (letting-be). Unlike ascetic self-torture, which Eckhart dismissed as another form of egoic ambition, *Gelassenheit* is the complete cessation of instrumental

teleology—acting *sunder warumbe* ("without a why"), the way life lives for its own sake rather than for an external payoff.

In the spring of 1327, when the Archbishop rejected his defense, the sixty-seven-year-old Eckhart walked five hundred miles south from Cologne to the Papal Court at Avignon to argue his propositions in person before a commission of cardinals. He died in Avignon before the verdict was delivered; on March 27, 1329, Pope John XXII issued the bull *In Agro Dominico*, condemning seventeen of his statements as heretical and eleven as dangerously suspect, while noting that Eckhart had submitted his writings to the judgment of the see before his death.

CHAPTER 7

The Rhenish Hermitage

Hildegard of Bingen and the Scivias Telemetry (1141–1151, Disibodenberg)

The illuminated plates of the twelfth-century manuscript *Scivias* depict concentric rings of blinding gold fire, jagged crenelated fortress walls, and showers of sparks that turn to black char against a dark field. In 1970, when neurologist Oliver Sacks compared those medieval parchment paintings against clinical drawings made by twentieth-century hospital patients, he identified the exact visual geometry of classical migraine aura: fortification spectra (teichopsia) and scintillating scotomas.

In the autumn of 1141, forty-two-year-old Hildegard sat inside the stone anchorhold attached to the Benedictine monastery of Disibodenberg above the Nahe River in the German Rhineland. Placed into the enclosure at age eight as a tithe by her noble parents, she had lived behind its stone walls for thirty-four years. Since age three, she had experienced recurring episodes of blinding visual light—what she called the *umbra viventis lucis* (“the reflection of the living light”)—accompanied by transient blindness, numbness, and days of physical prostration. Critically, unlike ecstatic trances, Hildegard never lost waking consciousness during an episode; she saw the geometric light arrays superimposed

directly over her open-eyed room while conversing with those around her.

In neurophysiology, migraine aura is driven by cortical spreading depression (CSD)—a self-propagating wave of intense neuronal and glial depolarization followed by transient electrical suppression that crawls across the grey matter of the primary visual cortex (area V1) in the occipital lobe at a fixed velocity:

$$v_{\text{CSD}} \approx 2 \text{ to } 5 \text{ mm/min}$$

Because the retinotopic map of human vision is laid out across the folded surface of V1 in orientation-selective columns, a three-millimeter-per-minute wave of potassium and glutamate efflux firing those columns in sequence generates an expanding crescent of shimmering zig-zag lines—resembling the angled bastions of a medieval walled city—followed by a temporary blind zone that resolves after twenty to sixty minutes.

For thirty-four years, fearing she would be diagnosed as demoniac, Hildegard kept the visual phenomena secret. In 1141, after a severe bout of illness, she began dictating her visual and auditory observations onto wax tablets with the assistance of the monk Volmar. When Pope Eugenius III read a draft of *Scivias* at the Synod of Trier in 1147 and granted papal authorization for her to publish, Hildegard turned the raw neurological telemetry of her visual cortex into an institutional lever.

Over the next three decades, she produced not only three volumes of visionary cosmology, but two encyclopedic treatises on empirical medicine and natural history (*Physica* and *Causae et Curae*), cataloging over two hundred local plants, minerals, and river fish with their German vernacular names, and recommending boiled water for wound cleansing and hops for preserving beer. She composed seventy-seven liturgical chants spanning two-and-a-half octaves that broke the narrow five-note bounds of Gregorian plainchant, invented a twenty-three-letter cipher alphabet (*Lingua Ignota*), and in 1150 defied the monks of Disibodenberg to move her nuns to an independent abbey at Rupertsberg equipped with gravity-fed indoor running water.

CHAPTER 8

The Hesychast Breath

Gregory Palamas and the Physiology of the Uncreated Light (1338–1351, Mount Athos)

In 1338, an Italian-Greek logician named Barlaam of Calabria arrived in Constantinople and began ridiculing the hermits of Mount Athos as *omphalopsychoi*—"men with their souls in their navels." Educated in the scholastic Aristotelianism of Western Europe, Barlaam was scandalized to learn that Athonite monks sat in darkened cells, bowed their chins to their chests, synchronized their breathing with a short mental phrase, and claimed that when mental chatter ceased, their physical nervous systems perceived an uncreated radiance. To Barlaam, God could only be approached indirectly through syllogistic reasoning and apophatic negation; any warmth, calm, or luminosity felt in the human torso was a physiological delusion.

From a hermitage high on the limestone cliffs of Mount Athos, forty-two-year-old Gregory Palamas—the son of a Byzantine imperial senator who had given up a career at court for monastic solitude—wrote the *Triads in Defense of the Holy Hesychasts*. Palamas agreed with Barlaam that the ultimate divine essence (*ousia*) remains forever beyond human perception. He countered, however, by drawing a structural distinction between inaccessible essence and radiated energy (*energeia*): just as a human eye cannot touch the

nuclear core of the sun without being vaporized yet directly receives its light across space, human biology can register and be reordered by uncreated energy without ceasing to be physical flesh.

The Athonite method of *hesychia* (stillness) defended by Palamas was a repeatable somatic biofeedback protocol:

- **Postural Compression**: Sitting on a low stool about nine inches off the floor in a quiet, unlit room, bowing the neck and resting the chin against the sternum while fixing visual convergence downward toward the midpoint of the chest.
- **Diaphragmatic Pacing**: Slowing inhalation and exhalation into a deep, even rhythm synchronized word-for-word with the silent mental repetition of the twelve-word Jesus Prayer.
- **Interoceptive Anchoring**: Withdrawing attention from cortical visual imagination and locking focus onto the physical sensation of the beating heart inside the ribcage.

In modern cardiorespiratory physiology, slowing a normal adult breathing rate of fifteen breaths per minute down to a paced cadence of roughly six breaths per minute hits the resonant frequency of the human baroreflex loop:

$$f_{\text{resonance}} \approx 0.1 \text{ Hz} \quad (6 \text{ breaths/min})$$

At 0.1 Hz, respiratory sinus arrhythmia—the natural acceleration of heart rate during inhalation and deceleration during exhalation—locks into exact phase resonance with

the ten-second Mayer waves of arterial blood pressure. Pressure receptors (baroreceptors) in the carotid sinus and aortic arch fire high-amplitude rhythmic bursts up the glossopharyngeal and vagus nerves into the nucleus tractus solitarius of the brainstem. Heart rate variability (HRV) amplitude quadruples, sympathetic vasoconstriction drops away, peripheral capillary beds dilate (producing a distinct physical sensation of warmth spreading across the chest), and cortical EEG activity shifts into synchronized alpha-theta coherence.

Between 1341 and 1351, the dispute between Barlaam's scholastic intellectualism and Palamas's embodied quietism became entangled in a Byzantine civil war. Palamas was imprisoned for four years in the imperial palace at Constantinople before being released and appointed Archbishop of Thessalonica. In July 1351, a council convened at the Blachernae Palace officially endorsed the Palamite somatic method as Orthodox doctrine, codifying a neurovisceral breathing discipline into the constitutional law of the Byzantine Empire.
